Statement of Academic Honesty

My name is: Safa Alasady, I declare that, except where fully referenced no aspect of this project has been copied from any other source. I understand that any act of Academic Dishonesty such as plagiarism or collusion may result in serious offense and punishments. I promise not to lie about my academic work, to cheat, or to steal the words or ideas of others, nor will I help fellow students to violate the Code of Academic Honesty.

Name: Safa Alasady Date: 2/29/2024

Signature: 

Introduction

Within most organizations, databases might be needed and if so, they are usually extremely important. A database is extremely important because it stores significant information. At a more specific level, databases stores things like entities and relationships. The purposes of databases are to store, maintain, and being able to access data. The project Zozo Company that I, the student, will complete, is about designing a complete database management system so that general information management tasks like retrieval of information for the company can be completed. It is important that details are exactly like how Zozo Company wants the database management system to be.

Project Description

The first step is to make a table that has all the attributes, keys, what data type these attributes and keys are, and if they are null or not null. Then create the conceptual, logical, physical ERD (entity-relationship diagram) in Erwin and Visio. After, create a supertype and subtype relationship with any entity in the ERD. It is important to make sure that all formats are followed, and that all entities, attributes, and relationships are accurately labeled. Based on the initial entities, it is important to show the functional dependencies and normalization.

Requirements

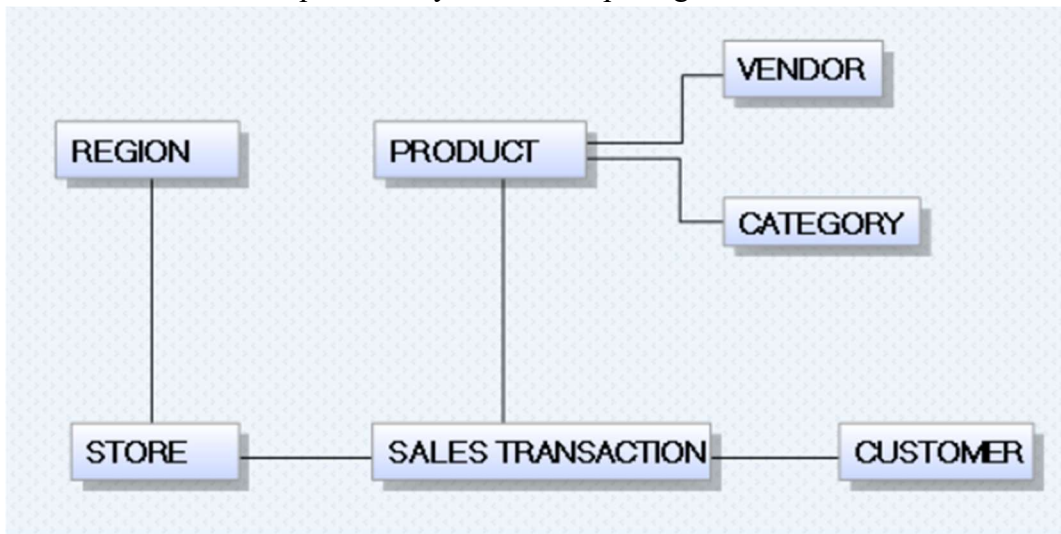

Requirements in the data models are initial entities, which are region, store, product, customer, and vendor. The following requirements for the database are for each product sold is product ID, product name, and price, for each category is category ID and category name, vendor is vendor ID and vendor name, store is store ID and zip code, and region is region ID and region name. There is also another entity which is sales transaction which formed by a bridge table with product and sales transaction, and it involves transaction ID and transaction date. There is only

one vendor which supplies one or more products. The product entity only belongs to one category and each category has one or more products. The store entity is in only one region and has one or more stores. The sale transaction happens only in one store and the store has one or more transactions happening. It also involves one customer, and each customer can be in one or more transactions. Besides the entity-relationship diagrams, the schemas for all relations, referential integrity constraints diagram, functional dependencies, and normalizations must be in alphabetical order, have proper capitalization, and lines between the relations.

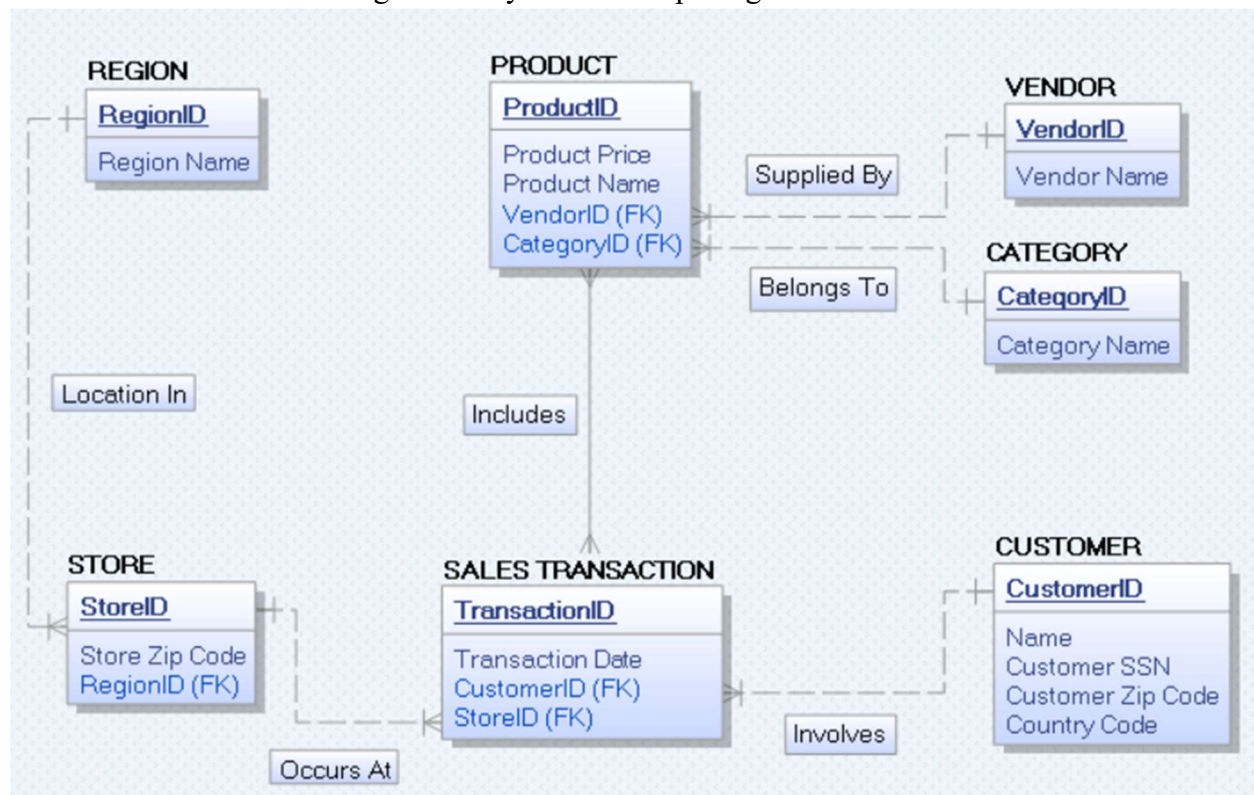

Attributes, Keys, Null/Not Null Data Type Table

Entity	Attributes	Data Type	Null/Not Null
Region	<u>RegionID</u> (PK)	integer(10)	Not Null
	Region Name	varchar(255)	Null
Store	<u>StoreID</u> (PK)	integer(10)	Not Null
	Store Zip Code	integer(10)	Null
	<u>RegionID</u> (FK)	integer(10)	Not Null
Product	<u>ProductID</u> (PK)	integer(10)	Not Null
	Product Price	numeric(19,2)	Null
	Product Name	varchar(255)	Null
	<u>VendorID</u> (FK)	integer(10)	Not Null
	<u>CategoryID</u> (FK)	integer(10)	Not Null
Includes	<u>TransactionID</u> (PK)	integer(10)	Not Null
	<u>ProductID</u> (PK)	integer(10)	Not Null
	Quantity	integer(10)	Null
Sales Transaction	<u>TransactionID</u> (PK)	integer(10)	Not Null
	Transaction Date	date	Null
	<u>StoreID</u> (FK)	integer(10)	Not Null
	<u>CustomerID</u> (FK)	integer(10)	Not Null
Vendor	<u>VendorID</u> (PK)	integer(10)	Not Null
	Vendor Name	varchar(255)	Null
Category	<u>CategoryID</u> (PK)	integer(10)	Not Null
	Category Name	varchar(255)	Null
Customer	<u>CustomerID</u> (PK)	integer(10)	Not Null
	Name	char(25)	Null
	Customer SSN	integer(9)	Null
	Customer Zip Code	integer(10)	Null
	Country Code	integer(10)	Null

Logical Entity Relationship Diagram in Erwin

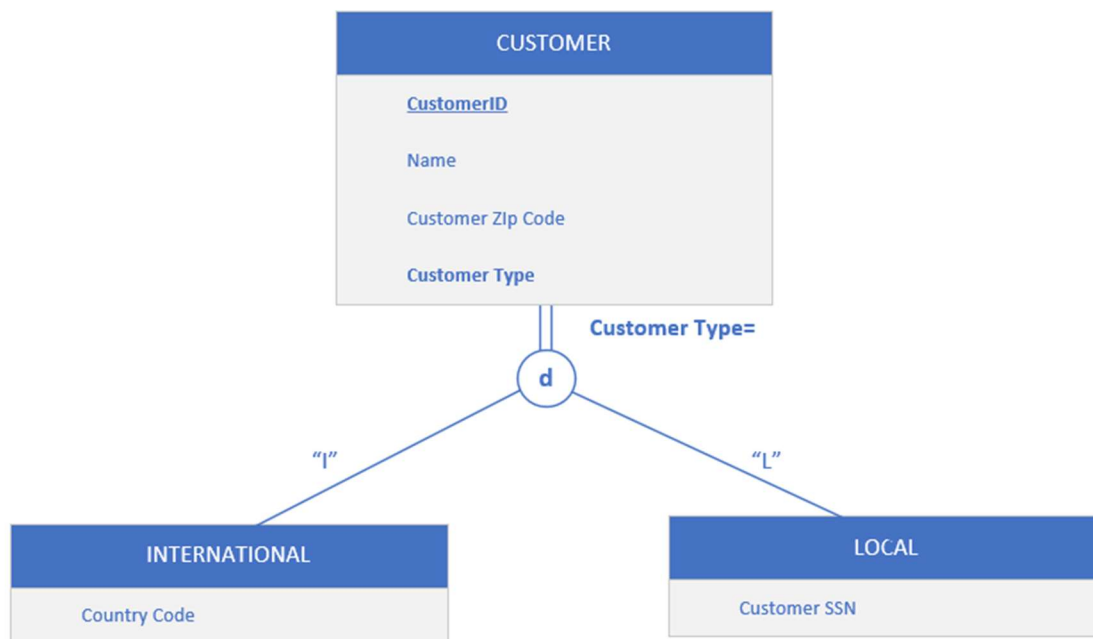

Physical Entity Relationship Diagram in Erwin

Physical Entity Relationship Diagram in Visio

Supertype/Subtype Relationship

This relationship is between one supertype **CUSTOMER**, and two subtypes **INTERNATIONAL** and **LOCAL**. It first started originally with **CUSTOMER** and it was understood that there could be different types of customers, international and local customers. In order to differentiate, Country Code is placed under **INTERNATIONAL** and to separate customers in the United States from international customers, Customer SSN is placed under **LOCAL**. This is disjoint because customers can be a member of only one subtype, not both. It is total specialization because customer must be a member of at least one subtype.

Schema For All Relations

CATEGORY

<u>CategoryID</u>	CategoryName
-------------------	--------------

CUSTOMER

<u>CustomerID</u>	CustomerName	CustomerZipCode	CountryCode	CustomerSSN
-------------------	--------------	-----------------	-------------	-------------

INCLUDES

<u>TransactionID</u>	<u>ProductID</u>	Quantity
----------------------	------------------	----------

PRODUCT

<u>ProductID</u>	ProductPrice	ProductName	<u>VendorID</u>	<u>CategoryID</u>
------------------	--------------	-------------	-----------------	-------------------

REGION

<u>RegionID</u>	RegionName
-----------------	------------

SALES TRANSACTION

<u>TransactionID</u>	TransactionDate	<u>StoreID</u>	<u>CustomerID</u>
----------------------	-----------------	----------------	-------------------

STORE

<u>StoreID</u>	StoreZipCode	<u>RegionID</u>
----------------	--------------	-----------------

VENDOR

<u>VendorID</u>	VendorName
-----------------	------------

Referential Integrity Constraints Diagram

CUSTOMER

<u>CustomerID</u>	CustomerName	CustomerZipCode	CountryCode	CustomerSSN
-------------------	--------------	-----------------	-------------	-------------

SALES TRANSACTION

<u>TransactionID</u>	TransactionDate	<u>StoreID</u>	<u>CustomerID</u>
----------------------	-----------------	----------------	-------------------

INCLUDES

<u>TransactionID</u>	<u>ProductID</u>	Quantity
----------------------	------------------	----------

PRODUCT

<u>ProductID</u>	ProductPrice	ProductName	<u>VendorID</u>	<u>CategoryID</u>
------------------	--------------	-------------	-----------------	-------------------

VENDOR

<u>VendorID</u>	VendorName
-----------------	------------

CATEGORY

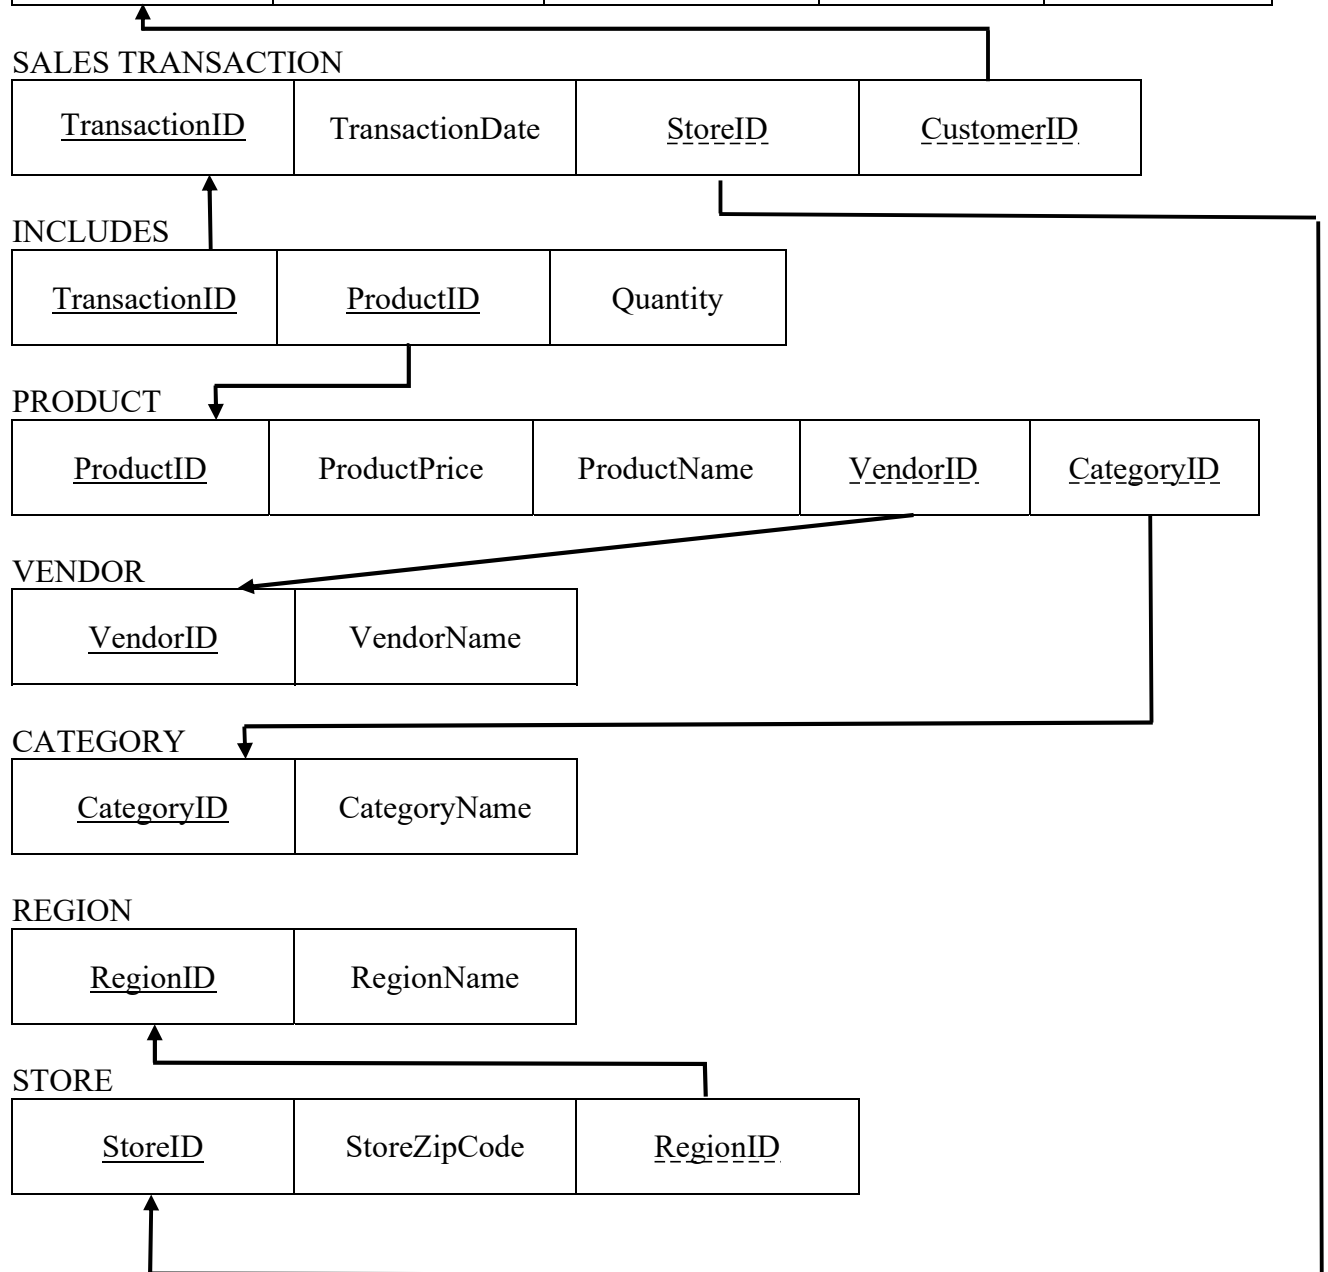

<u>CategoryID</u>	CategoryName
-------------------	--------------

REGION

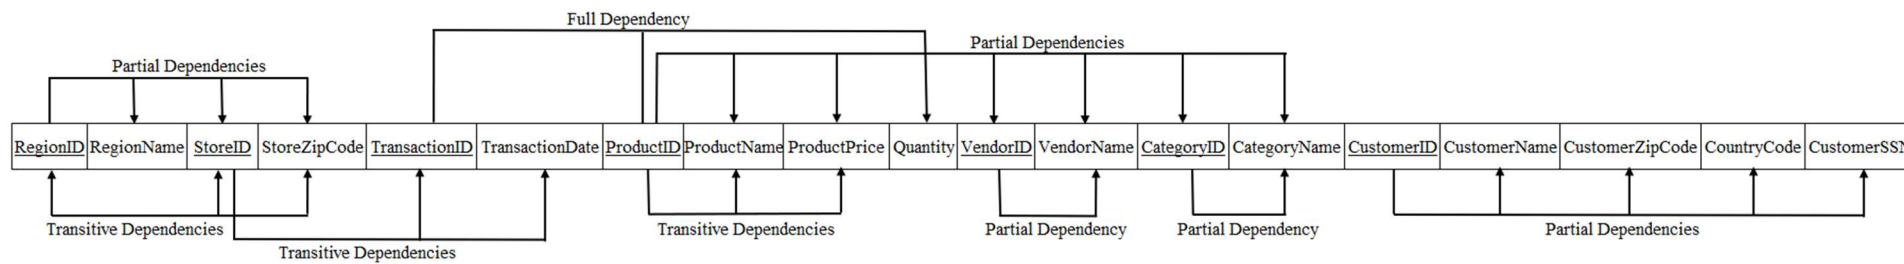

<u>RegionID</u>	RegionName
-----------------	------------

STORE

<u>StoreID</u>	StoreZipCode	<u>RegionID</u>
----------------	--------------	-----------------

Functional Dependencies

Normalization

<u>RegionID</u>	RegionName	<u>StoreID</u>	StoreZipCode	<u>TransactionID</u>	TransactionDate	<u>ProductID</u>	ProductName	ProductPrice	Quantity	<u>VendorID</u>	VendorName	<u>CategoryID</u>	CategoryName	<u>CustomerID</u>	CustomerName	CustomerZipCode	CountryCode	CustomerSSN
-----------------	------------	----------------	--------------	----------------------	-----------------	------------------	-------------	--------------	----------	-----------------	------------	-------------------	--------------	-------------------	--------------	-----------------	-------------	-------------

1NF

<u>CustomerID</u>	CustomerName	CustomerZipCode	CountryCode	CustomerSSN
-------------------	--------------	-----------------	-------------	-------------

CUSTOMER (3NF)

<u>TransactionID</u>	<u>ProductID</u>	Quantity
----------------------	------------------	----------

INCLUDES (3NF)

1NF

1NF

2NF

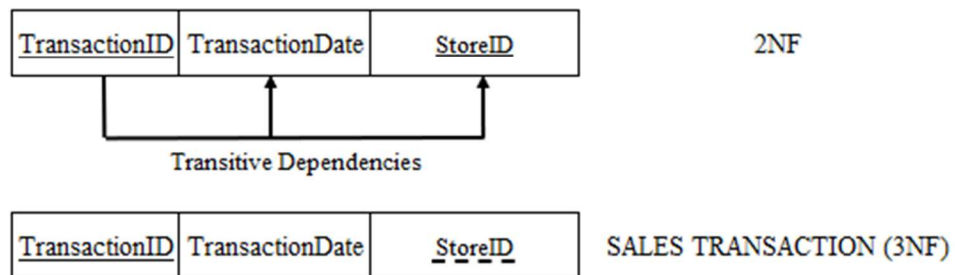

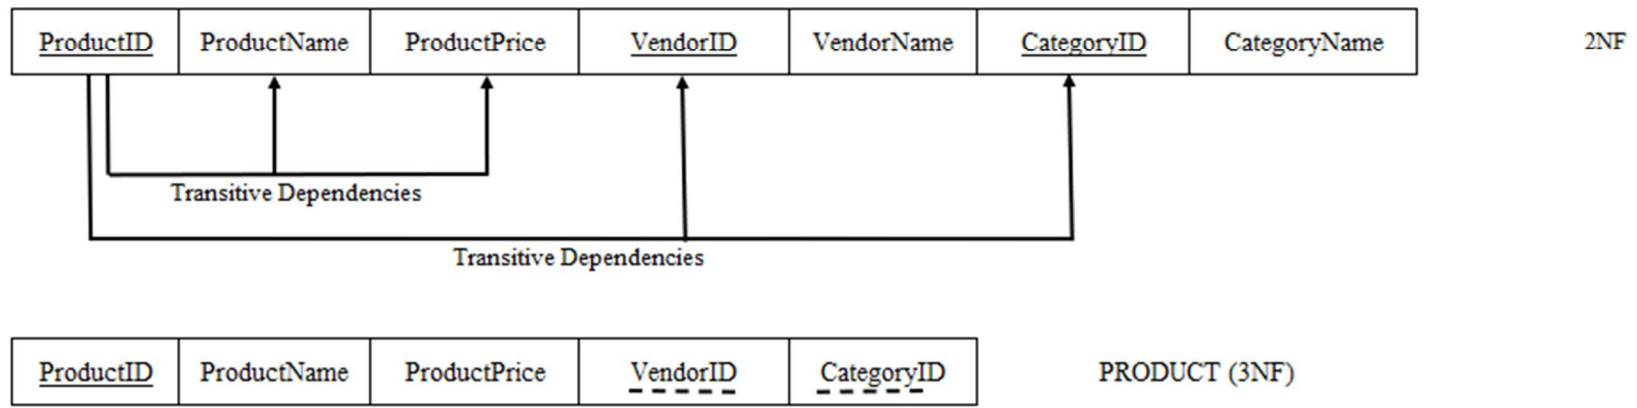

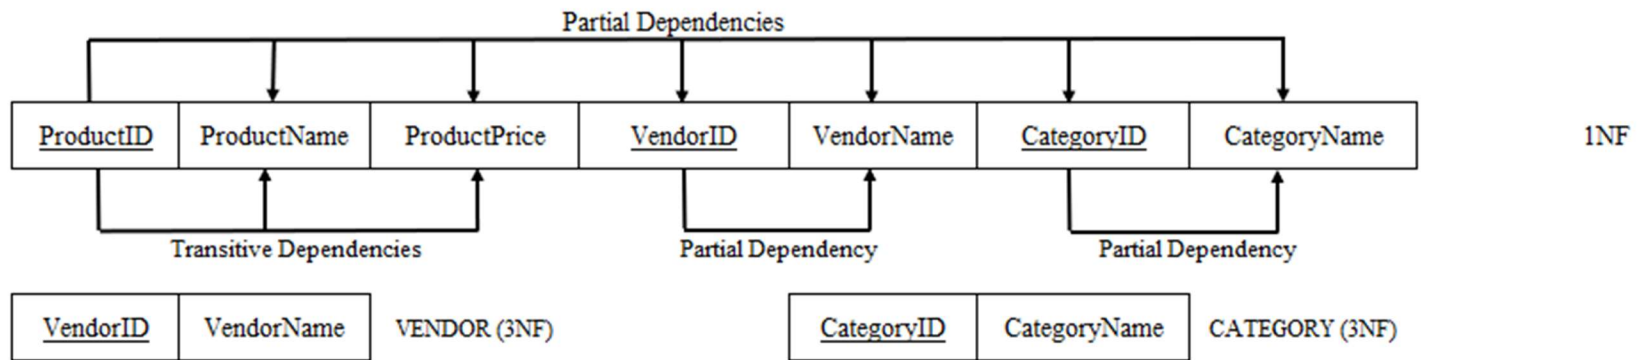

<u>RegionID</u>	RegionName
-----------------	------------

REGION (3NF)

Removed Partial Dependencies. RegionID and RegionName left with only Transitive Dependencies. Therefore, relation is in 3NF.

<u>StoreID</u>	RegionName	<u>RegionID</u>
----------------	------------	-----------------

STORE (3NF)

<u>CustomerID</u>	CustomerName	CustomerZipCode	CountryCode	CustomerSSN
-------------------	--------------	-----------------	-------------	-------------

CUSTOMER (3NF)

<u>TransactionID</u>	<u>ProductID</u>	Quantity
----------------------	------------------	----------

INCLUDES (3NF)

<u>RegionID</u>	RegionName
-----------------	------------

REGION (3NF)

<u>StoreID</u>	RegionName	<u>RegionID</u>
----------------	------------	-----------------

STORE (3NF)

<u>VendorID</u>	VendorName
-----------------	------------

VENDOR (3NF)

<u>CategoryID</u>	CategoryName
-------------------	--------------

CATEGORY (3NF)

<u>ProductID</u>	ProductName	ProductPrice	<u>VendorID</u>	<u>CategoryID</u>
------------------	-------------	--------------	-----------------	-------------------

PRODUCT (3NF)

<u>TransactionID</u>	TransactionDate	<u>StoreID</u>
----------------------	-----------------	----------------

SALES TRANSACTION (3NF)

Lessons Learned and Recommendations

Many lessons that were learned were being able to essentially replicate a real-life example of a database and how it would be implemented to complete database tasks like, collecting, updating, and retrieving information or data. Completing this project, I was able to understand how to use important data modeling programs, erwin Data Modeler and Microsoft Visio. Besides entity-relationship diagrams, I learned that business rules are crucial because they provide structure and consistency to relationships but is also primarily how the business operates. I also learned that relations are a key step in making sure that through the six properties of relations and referential integrity constraint, data stays organized and keeps data consistency.

I recommend that the requirements are more specified in the project instructions. There were many times where I was confused, and I needed to ask questions. To resolve this problem that I also see when talking to other students in the class would be showing an example or sample of the project to give some direction to students, or maybe even go through a short trail run of a creating database before assigning the project so that students already have an idea on how to start.

Conclusion

Databases play a critical role in organizations by acting as a system of important data. The Zozo Company project has a job which we must complete. The job is to create a database management system for their sales process that perfectly aligns with their requirements. The majority of this project was creating data models, relations, enhanced entity-relationship diagram in different programs with different requirements like business rules like one to one, one to many, and many to many, certain relationships, and proper formatting. Although this project was sometimes difficult and very confusing at times, I learned a lot about databases and how they work. It also pushed me to learn more about specific details about databases that I would not learn reading the textbook. I also made a lot of mistakes that I had to go back to correct, but it allowed me to learn how to identify these mistakes in a real-life setting. Completing this project showed that without databases, data would be not as organized compared to using a database, accessing data would be very difficult, and in general, make simple tasks difficult for organizations which is why databases are important to have.
